Interest in craniosacral therapy has exploded in recent years—not surprising given its gentle, effective approach to working on the spine and the skull and its cranial sutures, diaphragms, and fascias. The treatment focuses on the 92 percent of the human body composed of living water, rather than the eight percent that most therapies address. Building on the previous books, which explored underlying principles, differentiating the components of the practice, and combining theory and practice, this volume illustrates the evolution of craniosacral therapy over the past 30 years. More than 50 hand positions are presented in detailed photographs—many with multiple views—each of which can be used immediately and effectively. Additional chapters focus on the correct use and boundaries of the therapist’s hands, a precise sequence to follow when practicing biodynamically, and working with the therapist’s perception of the therapeutic process. Written for practitioners in the fields of massage, mental health, complementary and alternative medicine, and chiropractics, this book, like the others in the series, is equally useful read on its own or in sequence.

The human face is invariably interesting, even as an object of embryologic analysis. The early embryonic growth processes are located around the developing sense organs, among which the nose holds a key position. The first indication of the development of the nose is the formation of the placodes, oval areas of thick ened and condensed ectoderm, one on each side of the head. Each of these placodes is transformed, via the nasal groove, into the nasal tube, sometimes indicated as primitive nasal cavity. In the literature this transformation has been described as an isolated process that changes the superficial facial region. Some authors, including Wolgensinger (1950), think that the active component of this trans formation primarily is the ectoderm of the nasal placode. Others, i. e. Hochstetter (1891), Kallius (1905) and Vermeij-Keers (1967), assume this component be located in the mesenchyme. Peter (1913, 1949), Patten (1953, 1961), Warbrick (1960), and Andersen and Matthiessen (1967) hold both these components to be active. In the first and last of these three concepts the ectoderm of the nasal placode and the nasal groove respectively, is thought to invade the mesenchyme in the posterior direction. Invading ectoderm has also been considered to form - independent of the transformation - the organ of Jacobson and the naso lacrimal duct and to separate the conchae (e. g. Born, 1876; Legal, 1883; Kallius, 1905; Peter, 1913, 1949; Streeter, 1948; Andersen and Matthiessen, 1967).
